Free Parameters in the Standard Model (1/2)

28 free parameters of the Standard Model

- Masses of fermions (6 quarks, 6 leptons)
- couplings of the three interactions: g_W , α_{EM} , α_S
- Gauge Boson masses: m_Z and m_W
- Higgs-Sector: Shape parameters of potential λ, ν
- Flavour-Mixing: Two unitary matrices with (4 parameters each)
- CP-violating phase parameter in QCD $(\theta = 0)$

Fermion Masses and flavour mixing is decoupled from the rest. So we are left with: g_W , α_{FM} , α_S , ν , λ , m_W , m_Z

 $4 \Box Y + \Box P + 4 \Xi Y + \Xi Y = \Xi - 20 \Omega Q$

Free Parameters in the Standard Model (2/2)

We can rewrite these parameters, in terms of observables which we can measure very precisely in the experiment

$$
G_F = \frac{g_W^2}{4\sqrt{2}m_W^2}
$$

$$
e = g_W \sin \theta_W (\rightarrow \alpha_{EM})
$$

With the electroweak symmetry breaking we can expressed λ and ν with

$$
m_W = \frac{1}{2} g_W \nu
$$

This leaves us with four parameters which we can freely choose in the electroweak sector: G_F , α_{FM} , m_Z , m_H . And we will see in a seond that also m_t is important.

Radiative Corrections (1/2)

Let us look carefully at the m_W . It is given by

$$
m_W = \frac{\pi \alpha_{EM}}{\sqrt{2} G_F \frac{1}{\sin^2 \theta_W}}
$$

But a direct measurements yields to

$$
m_W^{ind}=78.1\pm0.4\,GeV
$$

$$
m_W^{direct} = 80.4 \pm 0.02 \, GeV
$$

6 / 22

What went wrong?

Radiative Corrections (2/2)

We have forgotten to take virtual loop corrections into account!

The W and Z Boson masses and coupling vertizes depends also on m_H and m_{ton} .

$$
m_{W,Z} \sim m_{top}^2 - ln(m_H^2)
$$

$$
\Delta \kappa \sim m_{top}^2
$$

By measureing m_W , m_Z and m_{top} precisely, we can estimate the mass of the SM-Higgs Boson! \rightarrow how do we measure this?

Idea of the W-Boson Mass Measurement (1/3)

For the Z boson it is easy, at least in principle

- Both decay leptons are measured in the calorimeters
- We can then combine their four-momenta and compute the invariant mass of the pair
- The distribution of this invariant should display a peak at the resonance. The position of the peak will give the resonance mass.

And for the W?

- We measure one decay lepton; the neutrino escapes
- We can however estimate the transverse momentum of the neutrino, by summing all measured signals in the calorimeter and imposing momentum conservation in the transverse plane!

8 / 22

Remember: E_T^{miss} !

Idea of the W-Boson Mass Measurement (2/3)

The transverse momentum distributions of the charged lepton and neutrino are sensitive to the W boson mass! Suppose the W is produced with longitudinal momentum (induced by the proton PDFs), and with small transverse momentum. Then in the W rest frame we have

$$
\frac{d\sigma}{d\text{cos}\theta} \sim 1 + \text{cos}^2\theta
$$

Change variables to

$$
p_T = \frac{m_W}{2} sin\theta
$$

and we get

$$
\frac{d\sigma}{dp_T} \sim \frac{p_T/m_W - (p_T/m_W)^3}{\sqrt{1 - (2p_T/m_W)^2}}
$$

Idea of the W-Boson Mass Measurement (3/3)

- **Hence the above relation** diverges at $p_T = m_W/2$.
- Divergence is cured by many effects, but a peak remains, allowing to estimate m_W from the distribution.

Template Fit method

- **•** Choose distribution which is sensitive to the parameter p
- \bullet Use different values of p at MC-generator level and produce new distributions
- Compare measured spectrum with generated

[1](#page-21-0)1 / 22

W-Boson Mass Measurement at Tevatron (1/3)

Use two observables

- Lepton transverse momentum p_T
	- \bullet m_W \sim 2p_T
	- **a** insensitive to recoil
	- $\rho_{\mathcal{T}}^W$ modelling crucial
- \bullet Transverse mass m_{τ}

$$
\bullet \ \ m_{\mathcal{T}}^2=2p_{\mathcal{T}}E_{\mathcal{T}}^{miss}(1-cos(\Delta\phi))
$$

- \bullet m_W \sim 2p_T + u_{||}
- low sensitivity to p_T^W
- Recoil modelling crucial

W-Boson Mass Measurement at Tevatron (2/3)

Event Selection

- Isolated, high p_T lepton (electron or muon)
- missing energy from neutrino
- A relative precision of 0.03% on m_W requires :
	- accuracy of lepton energy scale: 0.02accuracyofhadronicrecoilscale :1

Blind analysis

 \bullet m_W returned by fits was deliberately shifted by some unknown offset before the final fitting

W-Boson Mass Measurement at Tevatron (3/3)

Current most precise measurement from the CDF-experiment at Tevatron: $m_W = 80387 \hat{A} \pm 19 MeV$

• Expect to achieve a precision of < 10 MeV at the LHC

Transverse Mass

Transverse Momentum

 $\leftarrow 1 \rightarrow \leftarrow 13 \rightarrow 13 \rightarrow 22$ $\leftarrow 1 \rightarrow \leftarrow 13 \rightarrow 13 \rightarrow 22$ $\leftarrow 1 \rightarrow \leftarrow 13 \rightarrow 13 \rightarrow 22$

Measurement of the Z-Boson Mass (1/3)

We already performed a mass-measurement of the Z-Boson mass during the excersise:

- just plotted the invariant mass-spectrum of the decay muons
- peak-position was the Z-Boson mass

In principle we can use a similar template-fit approach as we used for the W-Boson mass

- Problem: Similar systematic uncertainties
- The LEP-experiments achieved a precision of 0.002%

Measurement of the Z-Boson Mass (2/3)

Remember the cross-section of the first lecture for $\sigma(\mathrm{e^+ e^-} \rightarrow \gamma \rightarrow \mu^+ \mu^-)$

$$
\sigma = \frac{4\pi\alpha^2}{3s}
$$

The cross-section changes when we introduce the Z-Boson. I.e. for $\sigma(\textup{e}^+\textup{e}^- \rightarrow Z \rightarrow f^+f^-)$ we get

$$
\sigma(e^+e^- \to Z \to f^+f^-) = \frac{12\pi}{s} \frac{\Gamma_{ee}\Gamma_{f_1f_2}}{(s-M_Z^2)^2 + s^2\Gamma_{tot}^2/M_Z^2}
$$

 $15 / 22$ $15 / 22$

Idea: Measure the cross-section at different collision energies s. Then fit line-shape (=cross-section prediction) $\rightarrow M_Z$

Measurement of the Z-Boson Mass (3/3)

Cross-section measurement is a simple counting problem

- just count how many Z-Bosons you observe in your detector
- many systematic, experimental uncertainties due not play a large role!

The Line-shape measurements at the LEP-colliders provide

- Very precise determination of the Z-Boson mass (and its width)
- Determination of the Weinberg mixing angle θ through the measurement for

Measurement of the Top-Quark Mass (1/2)

 $\begin{array}{ccc} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 &$ $\begin{array}{ccc} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 &$ $\begin{array}{ccc} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 &$

Selection of Top-Events: b-tagging! Background Processes: W+jets, Z+jets, WW, WZ, ZZ

Measurement of the Top-Quark Mass (2/2)

Top-Mass Measurement

- Basic idea as W-Boson mass \bullet
- Template Fit in reconstructed Top-Quark Mass
- Systematic Uncertainties
	- **o** Jet Energy Scale

Basic Idea

The precision measurement of $\alpha_{\sf s}, \alpha_{\sf EM}, {\sf G}_{\sf F}$ and $\theta_{\sf W}, {\sf m}_Z, {\sf m}_{\sf W}, {\sf m}_{\sf top}$ allows to

- **•** test if the predictions of the SM are consistent with the measurements
	- keep in mind: We have an overconstrained system
- **•** set a mass-range where the SM Higgs-Boson is expected:

 $19 \times 12 \times 12 \times 12 \times 12 \times 12 \times 12$ $19 \times 12 \times 12 \times 12 \times 12 \times 12 \times 12$

Indirect Determination of the Higgs-Boson Mass

- 1-sigma limit: $72 GeV < m_H < 119 GeV$
- 2-sigma limit: $50 GeV < m_H < 144 GeV$
- LEP Experiments: $114 \text{GeV} < m_H$

Why is $\alpha_{\sf s}$ important?

The following diagrams corresponding to final state strong interaction corrections

- QCD corrections suffer from large uncertainties
- **•** The choice of the electroweak observable of interest must be made such that the interpretation of its measurement is not plagued by unmastered QCD effects
- **•** Example
	- $\Gamma(Z \to bb)$ is subjected to a QCD correction at the level of 4% known to an accuracy of 20%
	- $\bullet \rightarrow$ Prefer to measure the partial width $\Gamma(Z \to bb)/\Gamma(Z \to hadrons)$ for which those corrections are suppressed by a factor 20. [2](#page-21-0)0 / 22

Results of the Electroweak Fit

Summary of Lecture 4

Precision Tests of the Standard Model allow the prediction of the SM Higgs-Boson mass Precision measurements of the W-Boson mass and the top-quark mass via template fits Precision measurement of the Z-Boson mass with lineshape fit
